

Veronesi's Sign: Bedside diagnosing Pancreas Cancer from Birth, i.e., its Inherited Real Risk.

By Sergio Stagnaro

All Authors around the world agree with the statement, the diagnosis of Pancreas Cancer is very difficult in symptomatic stage, but impossible in symptomless stages, as Oncological Terrain-Dependent, Inherited Real Risk of pancreas cancer.

Veronesi's Sign (1-5) allows physician for the first time to bedside diagnosing pancreas cancer from patient's birth, i.e., from its Inherited Real Risk.

In health, intense skin pinching ($1000 \text{ dyne/cm}^2 = 800\text{-}1300 \text{ gr.}$) at the level of one pancreas trigger-point, VI thoracic dermatome, doesn't bring about simultaneously (no-local realm in biological systems) the Gastric Aspecific Reflex: stomach fundus and body dilate, while antral pyloric region contracts) (Fig 1).

On the contrary, in individual involved by pancreas cancer, even in its Oncological Terrain-Dependent, Inherited Real Risk under identical experimental condition, simultaneously appears the Gastric Aspecific Reflex, followed immediately by tonic Gastric Contraction, whose intensity parallels the seriousness of underlying disorder.

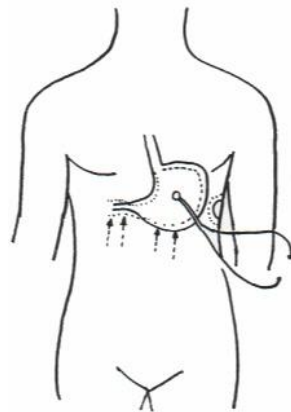

Fig 1.
